

SyncUp

Project ID: SyncUp

Reviewer: Assoc. Prof. Vítýzslav Beran, Ph.D. (using AI tools)

Project annotation

A user-friendly cross-platform appointment scheduling system designed to simplify booking meetings between students and professors.

Evaluation criteria

1. Relevance of the target product and its benefit (78%): The product solves a common and real problem inefficient scheduling of meetings between students and teachers. The benefit is clear: savings time, fewer misunderstandings and a central overview of consultations. The strength is the direct team's experience with the problem and role-based interface. The weaker point is that similar planning There are many tools and the proposal does not demonstrate why a separate solution should be created outside of integration with existing calendars.
2. Nature of the project (70%): The project is a practical software product with an application

character. Technological innovation is medium to low, as the core of meeting scheduling is common functionality, but interesting extensions are indoor mapping and integration with university calendars. The business character is not significantly developed; the project appears primarily as a university or academic service.

3. Product development, clarity of the product's target state and sufficient progress from the current state (82%): The current state is good: there is a deployed and available MVP, frontend-backend integration via Flutter and PocketBase is synchronized and supports availability, reservations, cancellations and user data. The target state in the competition adds indoor mapping, advanced scheduling conditions, integration with university calendars and broader testing. The shift is specific and builds well on the existing MVP.

4. Technological complexity (72%): The technological complexity is medium. Flutter and PocketBase allow for rapid development, but reliable conflict management, integration with university calendars or BUT IS, role-based permissions, notifications, and indoor navigation will be more complex. The proposal does not mention security, authentication with university accounts, synchronization with external calendars, or technical solutions for map data.

5. Design quality, relevance and completeness of information (76%): The design is clear, concise and lists a functional MVP, target functions and underlying technologies. The strong point is the clear definition of student and professor roles. The weak point is the less detailed description of architecture, testing, integrations, success metrics and deployment in a real academic environment. The financial plan is simple but lists basic operating costs.

Recommendation

SyncUp has a functional MVP and a well-defined next technological shift, which is positive for the competition. I recommend focusing less on general meeting scheduling and more on the differentiating technical parts: integration with the university calendar, availability rules, and indoor navigation to a specific room. Testing of booking conflicts, notifications, and permissions will be important for the quality of the product. For first-time users, a pilot deployment with a small group of teachers and students is suitable, measuring time savings, booking errors, and actual use of the system.
